

ASSIGNMENT_1

The next thing to do can be trying to implement handwriting synthesis in Graves Paper, which may incorporate bits of character embedding used in char_rnn. He found that a combination of character prediction, along with stroke prediction to be key to generating synthetic handwriting sequences that look natural, as the network needs to learn how certain strokes for a certain character flow into another character sequence.

Another interesting work is to incorporate Generative Adversarial Net approaches to recurrent network. Train a network to discriminate between fake handwriting and real one, and another network to generate fake handwriting to fool the discriminator network. This can be quite tough to do for RNNs though, although we must try anyways some are

thinking is that generative moment matching networks can perhaps be a better approach for generative RNNs as opposed to GANs.
